

Dynamic textures for facial animation

- Static textures enhance the realism of static geometry.
- Dynamic textures enhance the realism of moving geometry.

Synthesis codebook built from training video

- Record training video:
 - one speaker, constant lighting, head-mounted camera for constant pose
 - video contains 279 sentences, containing 6315 different triphone sequences.
- Build face model
 - Hand-label the significant points in a selection of images
 - Use principal components analysis (PCA) to build point distribution model (PDM)
 - Use PCA to build shape-free appearance model (SFAM): parameterises the variation of the texture map.

- Use models to track face in training video
 - gives equivalent model parameters for each frame.
- Build synthesis codebook
 - a continuous trajectory for each sentence passing through the model parameters for each frame.

Speech to face animation synthesis

Given a new phoneme sequence:

- extract sub-trajectories from original based on phonetic context
- concatenate sub-trajectories and apply to PDM and SFAM

Gesture notation for body animation

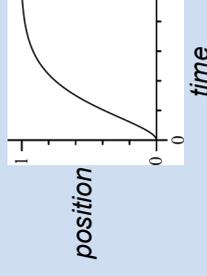

HamNoSys: avatar-independent transcription notation for sign languages, developed at the University of Hamburg.

Left hand points up/out/left, at shoulder level, to the left of the body; head and eyegaze turn left.

Automatic translation to animation data (joint rotations) for a specific avatar, using a description of the avatar's static body geometry.

Movement trajectories precomputed from a simplified control model, for several different sets of parameters.

Body animation data can be generated at up to 1000 frames/second = 2.5% of the time budget for 25 fps animation.
